# Computer vision: typical tasks

## Image classification

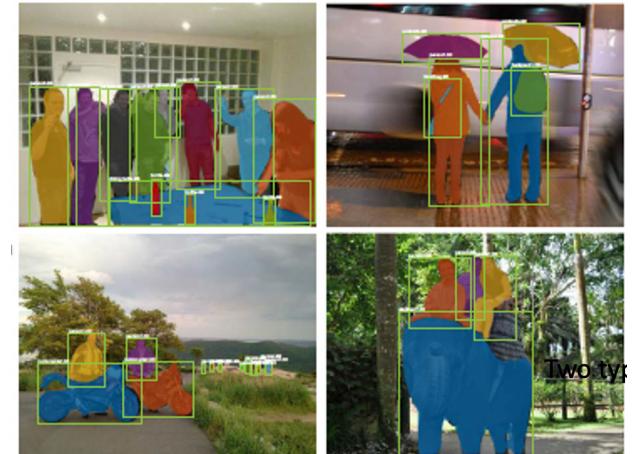

## Object Detection

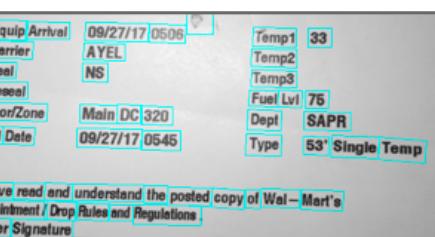

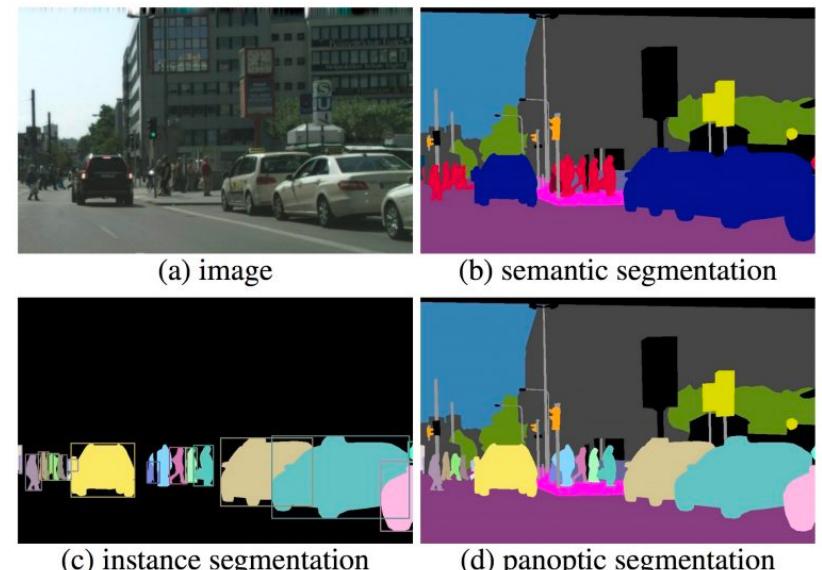

Redmon, J., Divvala, S., Girshick, R., & Farhadi, A. (2016). You only look once: Unified, real-time object detection. In *Proceedings of the IEEE Conference on Computer Vision and Pattern Recognition* (pp. 779-788).

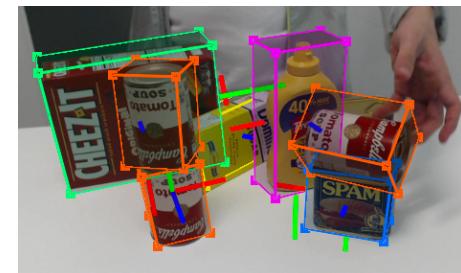

## Object segmentation

## Types of segmentation:

- 6D Pose estimation
- Optical character recognition (OCR)
- Face or fingerprint identification

# Computer vision: approaches

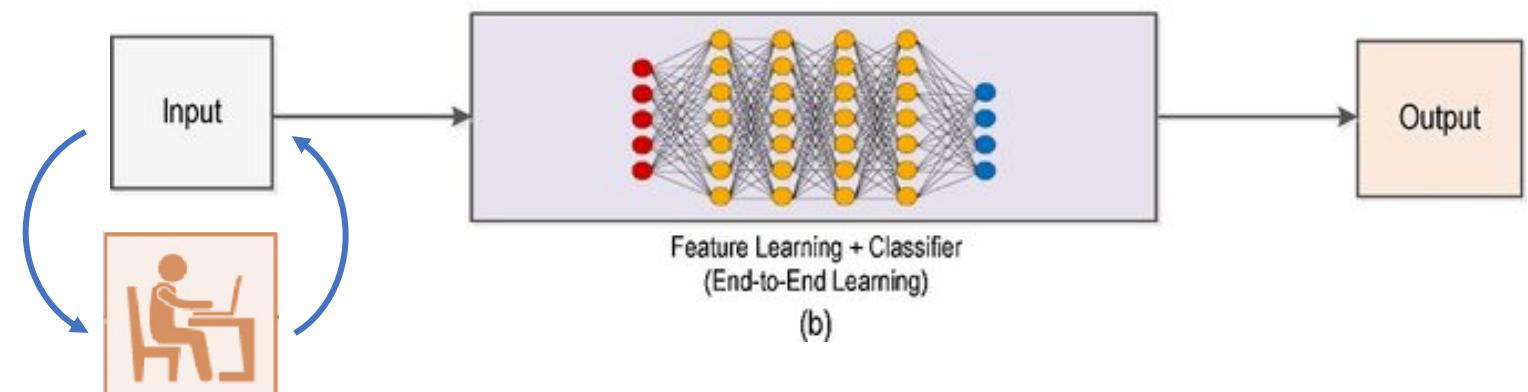

Traditional methods (developed since 1970s)

- Require feature extraction algorithms with many hand-tuned parameters
- Less power consuming than DL
- **New domain: tweaking parameters by hand**

Deep-learning (last 5-10 years)

- End-to-end approach: automatic feature extraction (feature map!)
- Nowadays: most of state-of-the-art approaches in CV employs deep-learning
- Needs much bigger datasets
- **New domain, problems with generalization: new dataset and/or domain adaptation methods**

Features learned from a deep neural net are **specific** to training dataset which, if not well constructed, probably won't perform well for images **different** from the training set

<https://arxiv.org/pdf/1910.13796.pdf>

- **image preprocessing**
- **dataset augmentation**

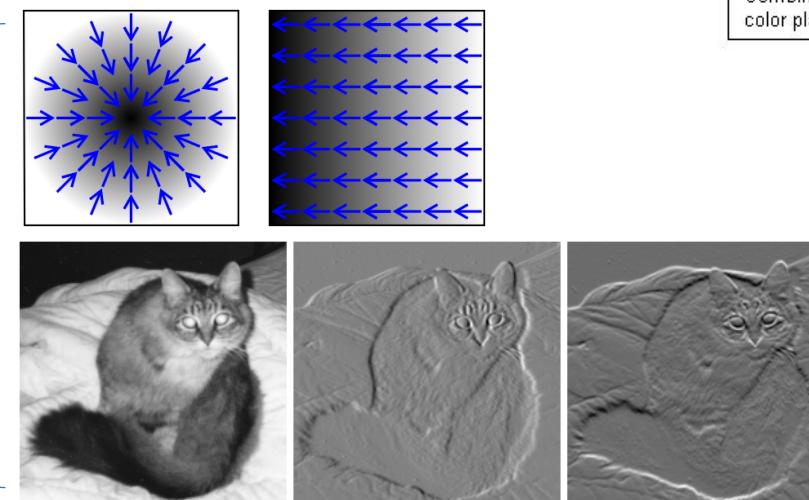

# Feature extraction

Features in computer vision: vector of numbers:

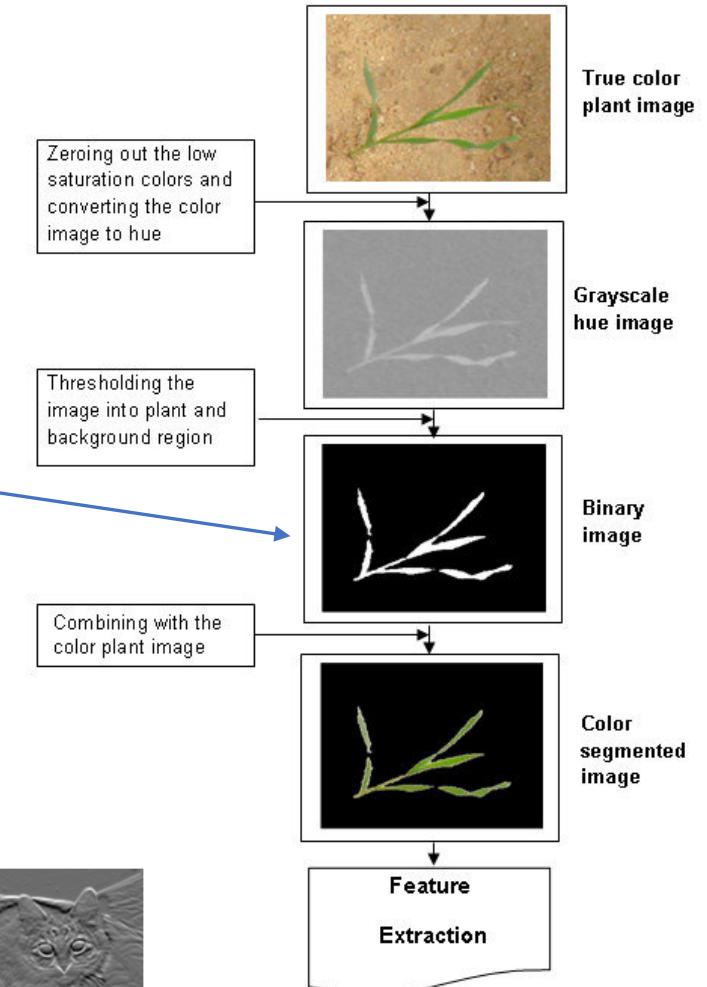

- characterizing whole image  
**(image classification)**
- describing interesting regions on images  
(e.g. keypoints or edges) with certain properties  
**(object detection)**
- Note that in CV community regions of interest (ROIs) itself are sometimes called *features* and numbers describing given region as *feature vector*

Region-feature vector extraction:  
(number calculated for each region)

- average of color (channel) magnitude
- pixel gradient or higher derivatives,  
e.g. Hessian matrix
- (local) histograms of pixel magnitudes
- region geometry attributes, such as the edge orientation

binary mask of  
interesting regions

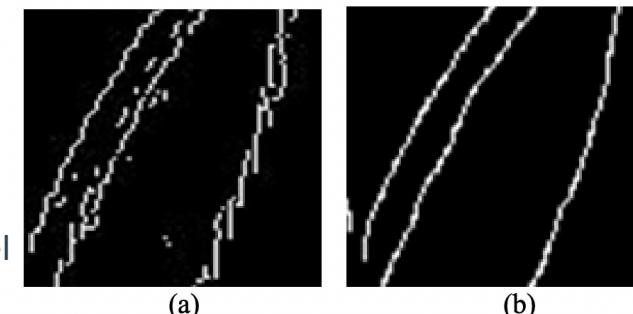

# Feature extraction

How to detect Interesting regions (or *features*)?

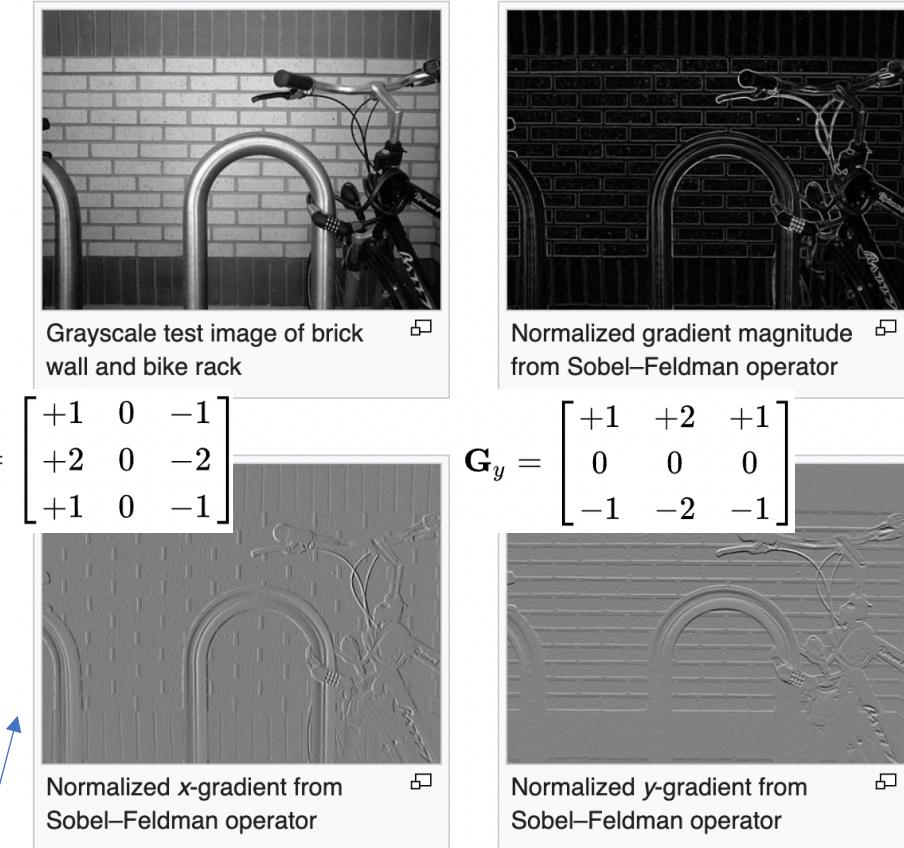

Edge detectors:

- **Sobel**
  - calculate approximation of the image gradient using convolution with Sobel kernels
  - apply threshold (intuition: regions with high gradient are likely edges)
  - other operators: Roberts, Prewitt
- **Canny**
  - multistage (denoising, edge operator, e.g. Sobel, then chose best pixel representing edge)
  - Canny edges are less noisy and straighter than ones from simple operators

Othman, Z. et al. "Comprison of canny and Sobel edge detection in MRI images." (2009).

Figure 3.0: The edge generated by Sobel (a) and Canny Edge (b) detection algorithms.

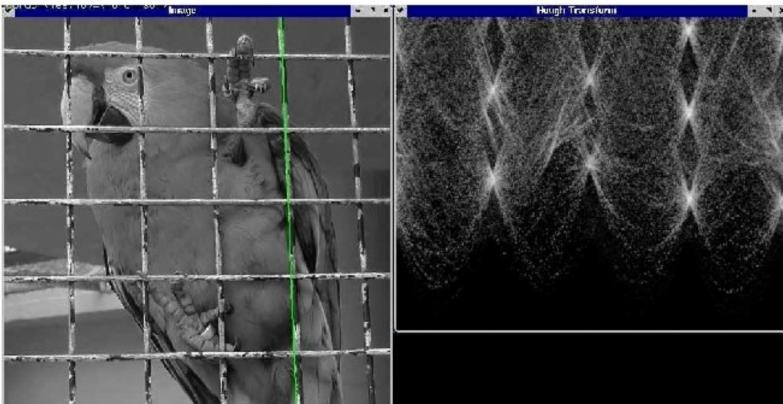

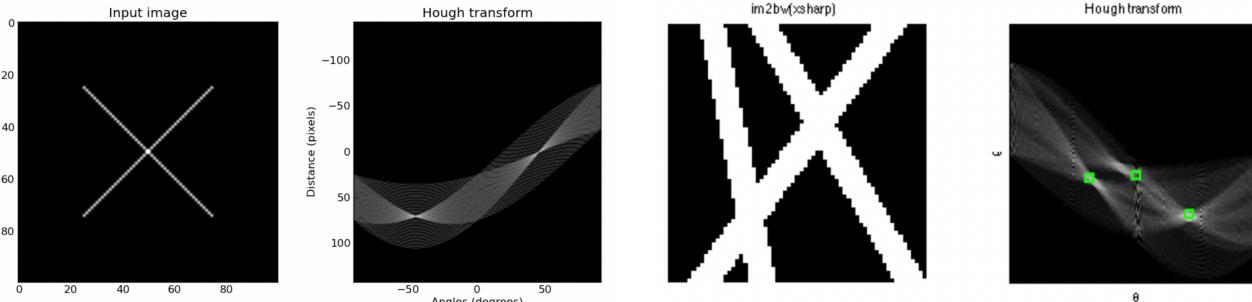

Convolution with kernel that approximates (minus) x-derivative

# Feature extraction

How to detect Interesting regions (or *features*)?

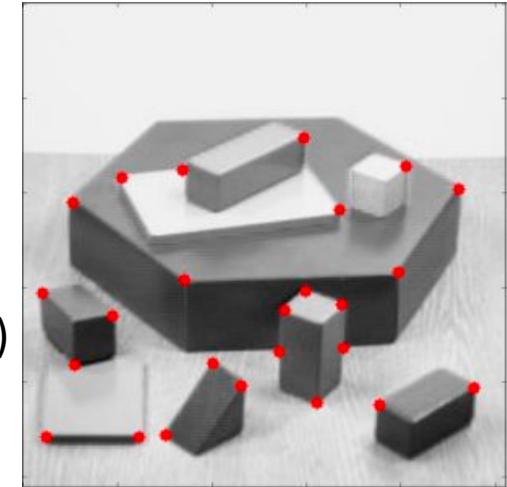

Straight line detection: **Hough transform**

Variation: circle/ellipse shape detection

## Corner detection

- Plethora of algorithms
- can be interpreted as the junction of two edges
- Idea: analyze local differences (possible edges) in orthogonal directions at once

Simple example -- Harris detector:

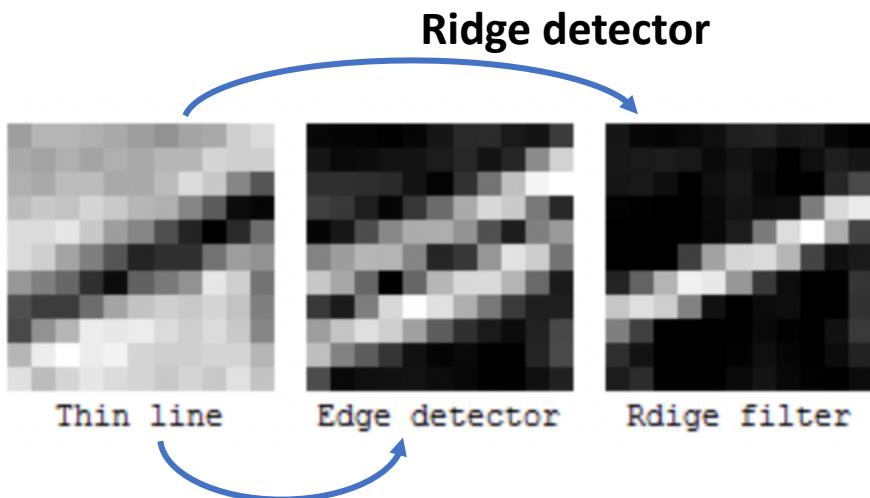

- analyze *structure tensor* ( $I$  = pixel intensity map)

$$\begin{bmatrix} \sum_{(x,y) \in W} I_x^2 & \sum_{(x,y) \in W} I_x I_y \\ \sum_{(x,y) \in W} I_x I_y & \sum_{(x,y) \in W} I_y^2 \end{bmatrix}$$

- partial derivatives of Image with respect to x and y in corner: both eigenvalues are large

# Feature extraction

How to detect Interesting regions (or *features*)

<https://dsp.stackexchange.com/questions/1714/best-way-of-segmenting-veins-in-leaves>

*edges* = borders between extended areas of high value,  
*ridges* = thin lines darker or brighter than their neighborhood),  
• edge filter will give two flanks, one on each side of the elongated object, and a low response in the middle of it,  
• ridge detector gives single mark that might be easier to analyze

## Blob detection

a blob is a region of an image in which some properties are constant or approximately constant

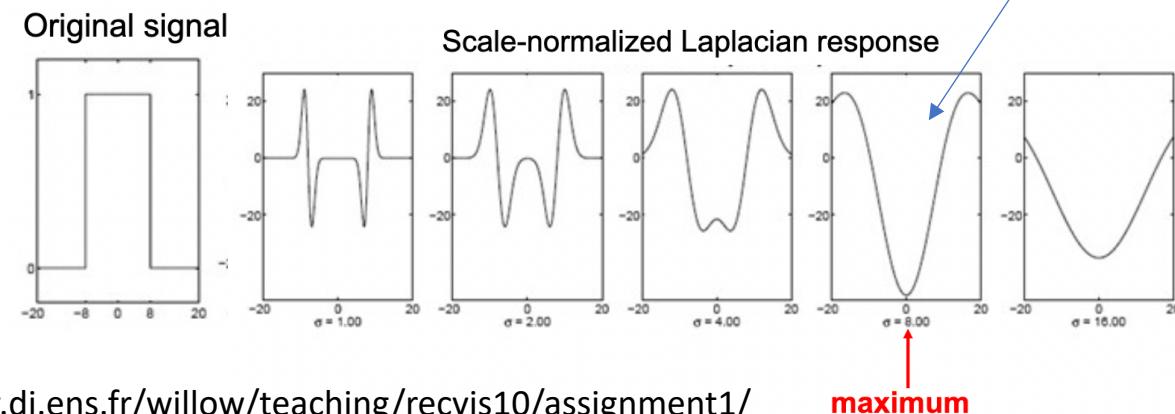

<https://answers.opencv.org/>

$$\nabla_{norm}^2 L = t(L_{xx} + L_{yy})$$

$$L(x, y; t) = g(x, y, t) * f(x, y) \quad g(x, y, t) = \frac{1}{2\pi t} e^{-\frac{x^2+y^2}{2t}}$$

Characteristic scale

# Feature extraction

## Multiscale Feature descriptors:

- **SIFT**
  - Histograms of image gradient at key positions on image (*keypoints*)
- **SURF**
  - Faster than SIFT
  - Feature descriptor uses wavelet decomposition than gradients
- **BRIEF**
  - Very fast regions of interest descriptor
  - Needs additional method to extract ROIs
  - and many others

medium.com

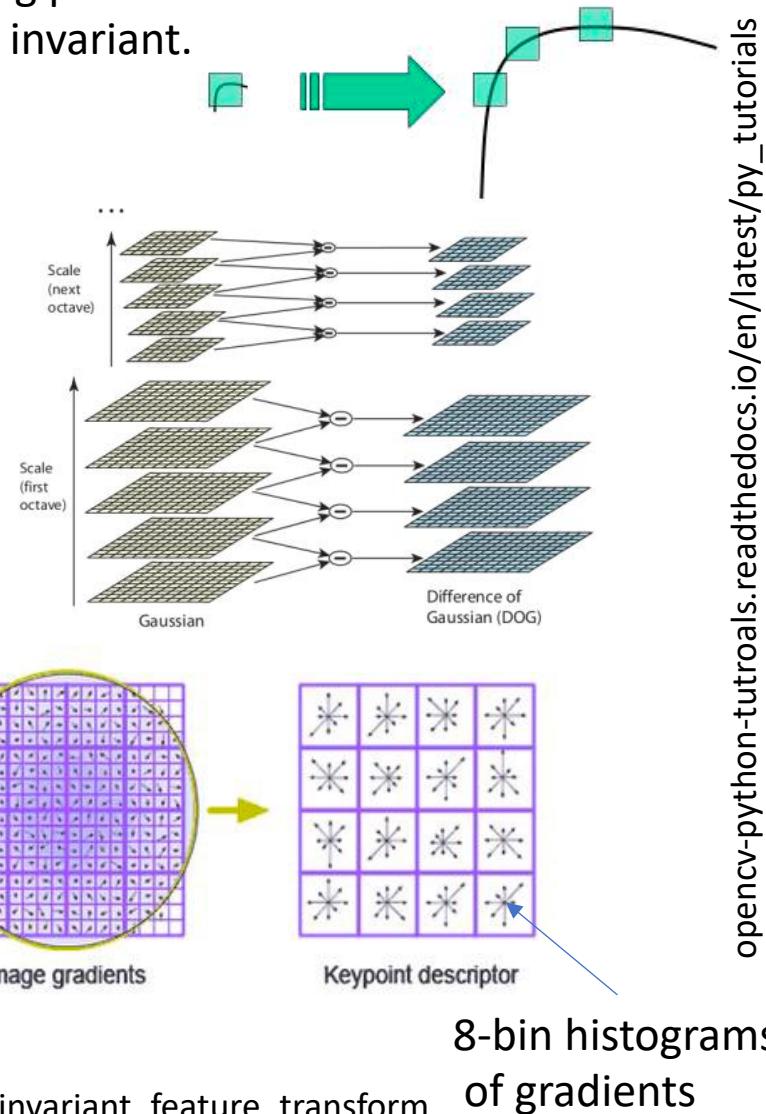

### SIFT algorithm

- keypoint detection at different scales:
  - detect blobs at different scales using Laplacian operator (approximated by difference of Gaussian convolutions with different sigmas)
  - then local extrema on DoG maps are founded as keypoints
- keypoint descriptor: histogram of grad.

en.wikipedia.org/wiki/Scale-invariant\_feature\_transform

Scaling problem: corner here is not scale invariant.

# Image preprocessing

## Preprocessing

- simple: morphological filtering
- histogram equalization
- colors intensity normalization (important in deep-learning):

## TORCHVISION.MODELS

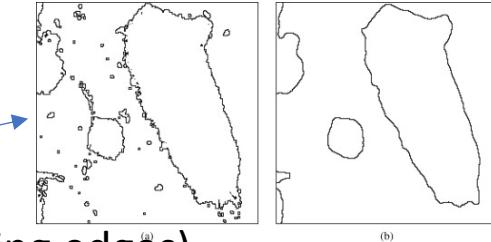

All pre-trained models expect input images normalized in the same way, i.e. mini-batches of 3-channel RGB images of shape  $(3 \times H \times W)$ , where  $H$  and  $W$  are expected to be at least 224. The images have to be loaded in to a range of  $[0, 1]$  and then normalized using `mean = [0.485, 0.456, 0.406]` and `std = [0.229, 0.224, 0.225]`. You can use the following transform to normalize:

```
normalize = transforms.Normalize(mean=[0.485, 0.456, 0.406],  
                                std=[0.229, 0.224, 0.225])
```

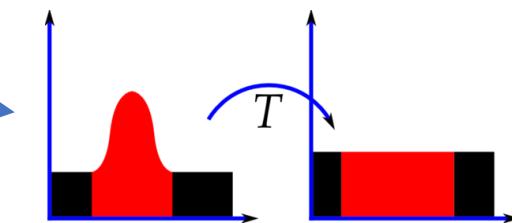

An example of such normalization can be found in the imagenet example [here](#)

## Filtering:

- median (usable for salt & pepper noise)
- morphological (for enhancing binary images/masks)
- anisotropic diffusion (strong denoising while preserving edges)

N. Galatsanos et al., "Digital Image Enhancement" (2003).

[en.wikipedia.org/wiki/Histogram\\_equalization](https://en.wikipedia.org/wiki/Histogram_equalization)

ImageNet parameters  
commonly used in CV  
to normalize images

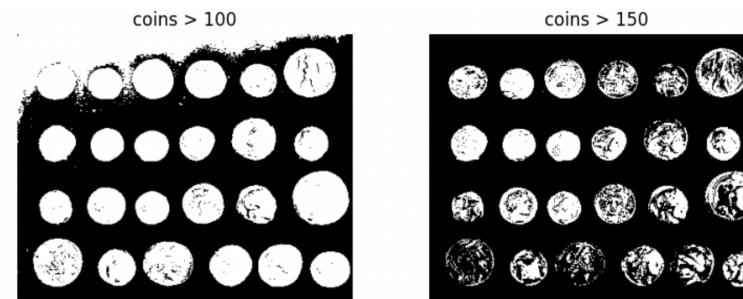

# Segmentation

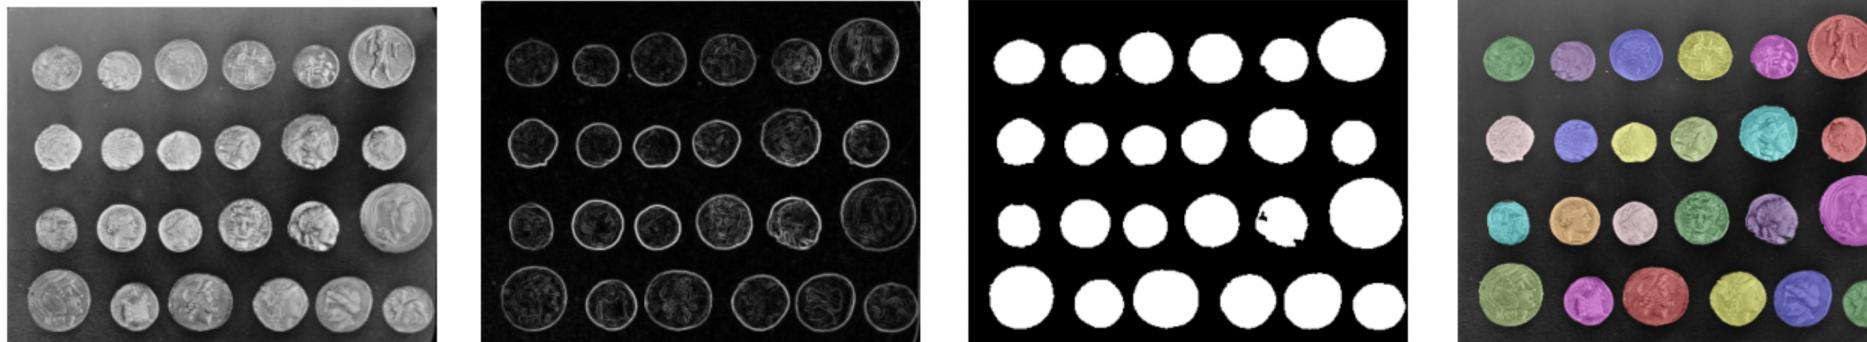

Segmentation: partitioning image into multiple segments (objects)

Traditional approaches:

- thresholding, e.g. Otsu method (automatic threshold)
- edge detection
- watershed
- k-means

Thresholding  
text segments

Image

## Region-based segmentation

Let us first determine markers of the coins and the background. These markers are pixels that we can label unambiguously as either object or background. Here, the markers are found at the two extreme parts of the histogram of grey values:

```
>>> markers = np.zeros_like(coins)
```

Global thresholding

## Region-based segmentation

determine markers of the coins and the background. These markers are pixels that we can label unambiguously as either object or background. Here, the markers are found at the two extreme parts of the histogram of grey values:

```
>>> markers = np.zeros_like(coins)
```

Adaptive thresholding

## Region-based segmentation

Let us first determine markers of the coins and the background. These markers are pixels that we can label unambiguously as either object or background. Here, the markers are found at the two extreme parts of the histogram of grey values:

```
>>> markers = np.zeros_like(coins)
```

# Segmentation

Segmentation: partitioning image into multiple segments (objects)

Traditional approaches:

- thresholding, e.g. Otsu method  
(automatic threshold)
- edge detection
- watershed
- **k-means**

Note: this is not just simple  
geometrical distance

The [K-means algorithm](#) is an [iterative](#) technique that is used to [partition an image](#) into  $K$  clusters.<sup>[19]</sup> The basic algorithm is

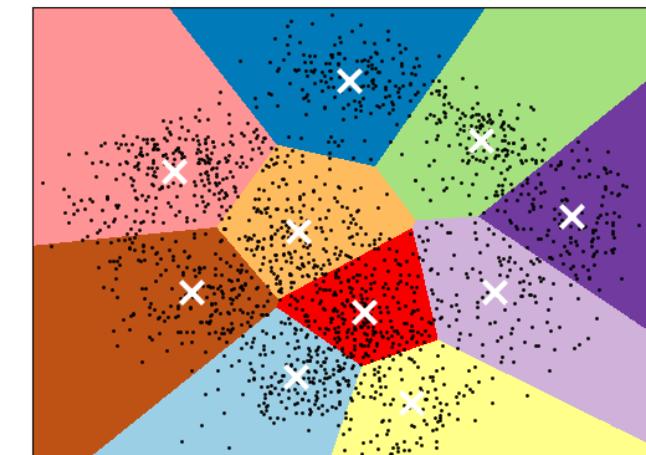

1. Pick  $K$  cluster centers, either [randomly](#) or based on some [heuristic](#) method, for example [K-means++](#)
2. Assign each pixel in the image to the cluster that minimizes the [distance](#) between the pixel and the cluster center
3. Re-compute the cluster centers by averaging all of the pixels in the cluster
4. Repeat steps 2 and 3 until convergence is attained (i.e. no pixels change clusters)

In this case, [distance](#) is the squared or absolute difference between a pixel and a cluster center. The difference is typically based on pixel [color](#), [intensity](#), [texture](#), and location, or a weighted combination of these factors.  $K$  can be selected manually, [randomly](#), or by a [heuristic](#). This algorithm is guaranteed to converge, but it may not return the [optimal](#) solution. The quality of the solution depends on the initial set of clusters and the value of  $K$ .

Not to be confused with *k-nearest neighbors supervised classifier*

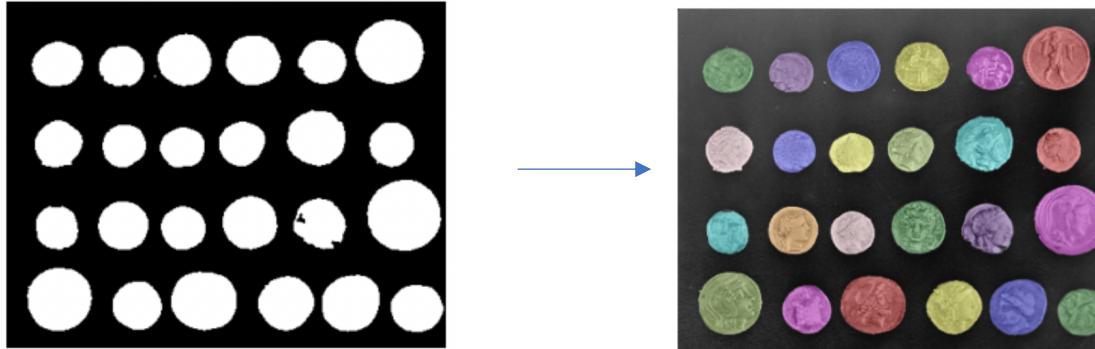

Voronoi tessellation with  
specifically defined metric

K-means clustering on the digits dataset (PCA-reduced data)  
Centroids are marked with white cross

# Clustering

How to color these segments?

Cluster analysis, some popular algorithms:

- k-means
- spectral clustering
- Hierarchical clustering
- DBSCAN/OPTICS

Generalization to n-D space:  
clustering of unlabeled data is type of **unsupervised learning**

Plethora of algorithms

Crucial parameter: number of clusters

- Few vs dozens (e.g. spectral vs hierarchical clustering)
- # of clusters to be specified in advance or not (e.g. DBSCAN don't need it)
